Robotics

Robotics is a great field, continually expanding. Many manufacturers currently use a form of robotics to facilitate manufacturing of products given the high demand.

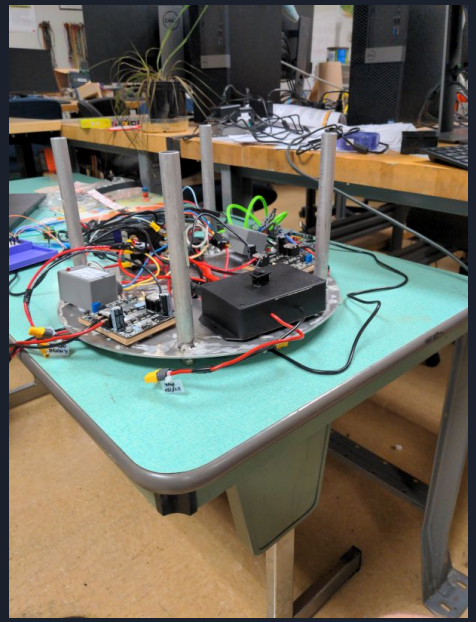
Autonomous driving is also a field of robotics being currently tested, and many big companies such as Tesla, Ford, and others currently search for a solution.

The Client: Dr. Leverington

- Lecturer of Computer Science at NAU
- Wants a “wow” factor to bring in new engineering students
  - Do this by making a robot that can give tours
  - Provide a platform for students to learn robotics

Problem Overview

- Robots are expensive to build
  - Need an affordable robot that can give tours and easy to build
- Autonomous navigation module can be difficult to implement, given the vast amount of variables that may be present, such as obstacles.
- Obstacle avoidance must also be recognized and handled appropriately.



The Thirty Gallon Robot

What is the robot, the overall goal:

- Full touring implementation requires multiple modules operating together
- Obstacle avoidance and autonomous movement are crucial implementations for further development
- Stepping stone for learning about robotics

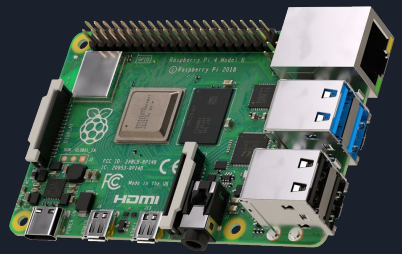
Project challenges:

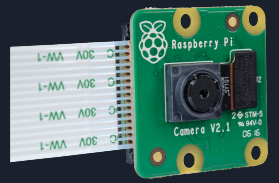
- The hardware doesn't move on its own.
- Currently no software architecture that employs the use of the components.

Solution Statement

We are focused on implementation of phase one. Our plan is to implement two major modules:

- Autonomous Movement
- Obstacle Avoidance





Implemented with:

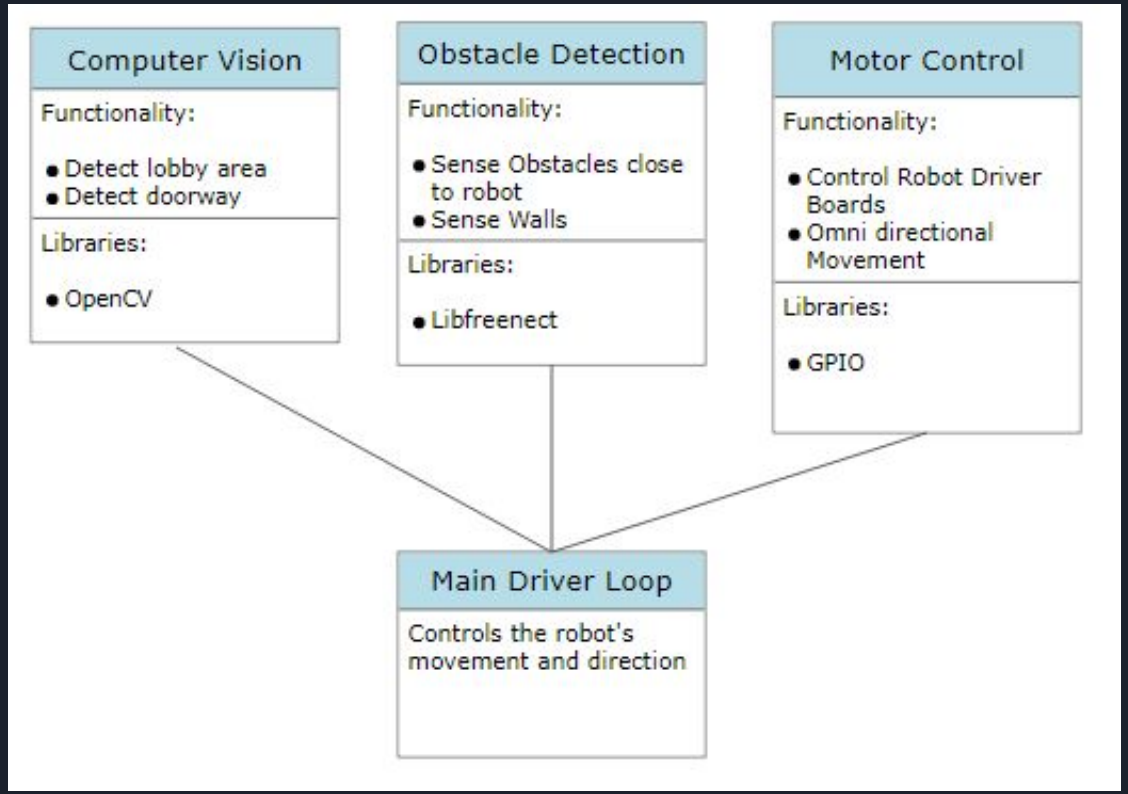
- Robot uses a raspberry pi as the central computer and controller.
  - Controls motors
- Kinect sensor for detecting obstacles
  - Tells the pi when it should avoid an object
- Small camera module for end of hallway detection
  - Image classification/recognition

Requirements

- Autonomously move down the long hallway of the second floor engineering building
  - Move at the average human walking speed
- Avoid any obstacles in the way
  - These obstacles may be random
  - 1 to 3 meters away
  - At least ½ meter tall
- Detect when the robot has reached the end of the hallway
- Be able to turn around and come back
- Detect when it has returned the starting point and stop moving

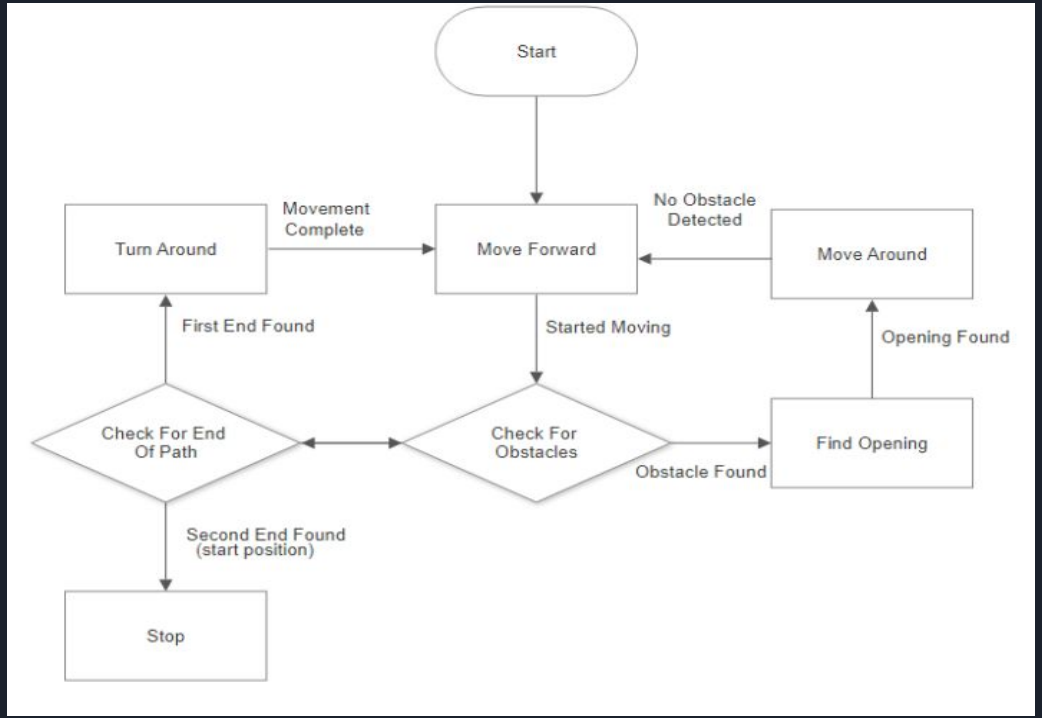
Architecture Overview

- Computer Vision:
  - OpenCV
  - Allow camera access
  - Machine learning
- Obstacle Detection:
  - Libfreenect
  - Allow Kinect Sensor access
  - Object detection
- Motor Control
  - GPIO
  - Allows access to motors
  - Robot movement



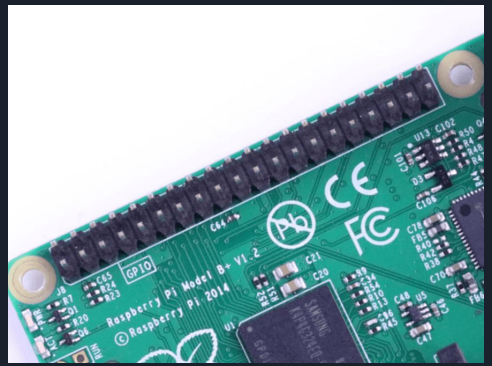
Implementation Overview

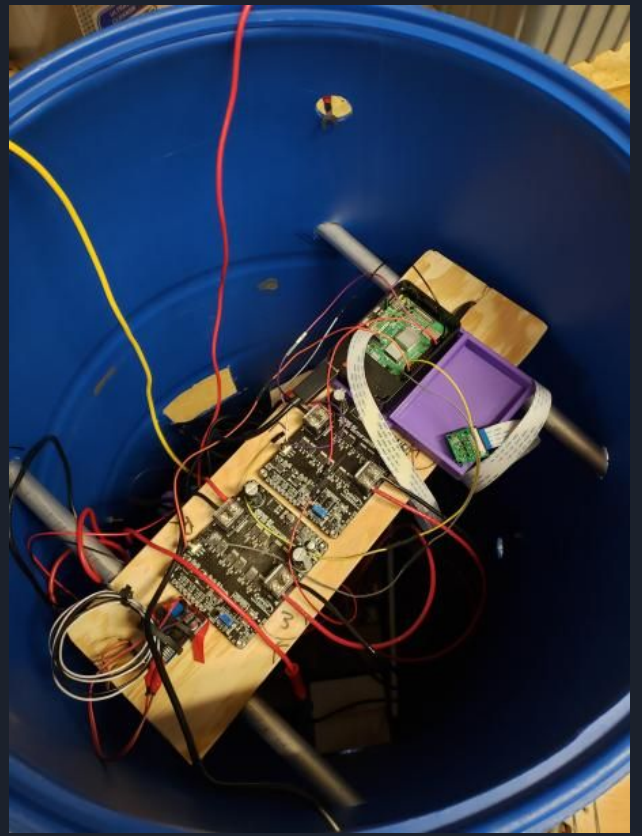
- One main loop
  - Does constant checking for obstacles and end of hallway conditions
- Checks for two end of hallway conditions
- Checks for obstacles in path



Prototype Review - Autonomous Movement

- Hardware connection between the Raspberry Pi's GPIO pins and the motor driver pins
- Provides interface that may be called upon in the program:
  - move_forward()
  - move_backward()
  - turn_left()
  - turn_right()
  - stop()





Prototype Review - Obstacle Detection

- The kinect sensor is opened and the depth images are taken and processed
- The side in which an obstacle lies on will be determined and rotate the robot in the opposite way

```
rpi@rpi:~/ThirtyGallon$ python3 main.py
======================== PROGRAM STARTING ========================
Trying To Open Kinect...
Kinect Opened
Moving Forward
Checking for Obstacle
Obstacle Found, Waiting 3 seconds --------------------------------

XXXXXXXXXXXXXXXXXX|Obstacle On Right Side
<<<<< Turning Left <<<<<

Opening Found, Continuing ----------------------------------------
Moving Forward
Checking for Obstacle
```

Prototype Review - Opening Detection

- The robot moves in the direction away from the obstacle. During this it is using a similar method to detect an opening.
- Finding an opening resulting in the robot continuing forward down its path

```
rpi@rpi:~/ThirtyGallon$ python3 main.py
======================== PROGRAM STARTING ========================
Trying To Open Kinect...
Kinect Opened
Moving Forward
Checking for Obstacle
Obstacle Found, Waiting 3 seconds --------------------------------

XXXXXXXXXXXXXXXXXX|Obstacle On Right Side
<<<<< Turning Left <<<<<

Opening Found, Continuing ----------------------------------------
Moving Forward
Checking for Obstacle
```

Prototype Review - Hallway Detection

- The end of the hall detection is done on a separate thread. It constantly gathers the image from the Raspberry Pi Camera and predicts the outcome from the machine learning model
- In order to account for false positives we check that the camera detects the same end of the hall multiple times consecutively.
- The first end detection results in the robot turning around, and the second ends the program.

```
rpi@rpi:~/ThirtyGallon$ python3 main.py
======================== PROGRAM STARTING ========================
Trying To Open Kinect...
Kinect Opened
Moving Forward
Checking for Obstacle
Obstacle Found, Waiting 3 seconds --------------------------------

Obstacle On Left Side|XXXXXXXXXXXXXXXXXX
>>>>> Turning Right >>>>>

Opening Found, Continuing ----------------------------------------
Moving Forward
Checking for Obstacle
Result = LOBBY     Lobby +++: 1  |  Door +++: 0
Result = LOBBY     Lobby +++: 2  |  Door +++: 0
Result = LOBBY     Lobby +++: 3  |  Door +++: 0

END OF HALLWAY - LOBBY
TURNING AROUND

Obstacle Found, Waiting 3 seconds --------------------------------

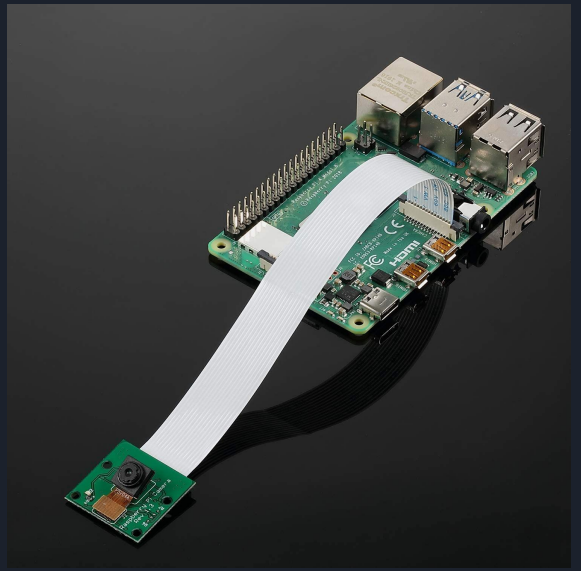
XXXXXXXXXXXXXXXXXX|Obstacle On Right Side
<<<<< Turning Left <<<<<

Opening Found, Continuing ----------------------------------------
Moving Forward
Checking for Obstacle
Result = DOOR      Lobby +++: 0  |  Door +++: 1
Result = DOOR      Lobby +++: 0  |  Door +++: 2
Result = DOOR      Lobby +++: 0  |  Door +++: 3

END OF HALLWAY - DOOR
STOPPING PROGRAM
======================== PROGRAM ENDED ========================
```

Challenges and Resolutions

- Detecting the end of the robot's path
  - Implementing a small camera
  - Using AI to model and recognize the end of the path
  - Kinect infrared sensor impacted by sunlight
- Electrical issues with robot
  - Getting the robot re-built with more sound architecture
  - Reengineer power module and drivetrain for the robot

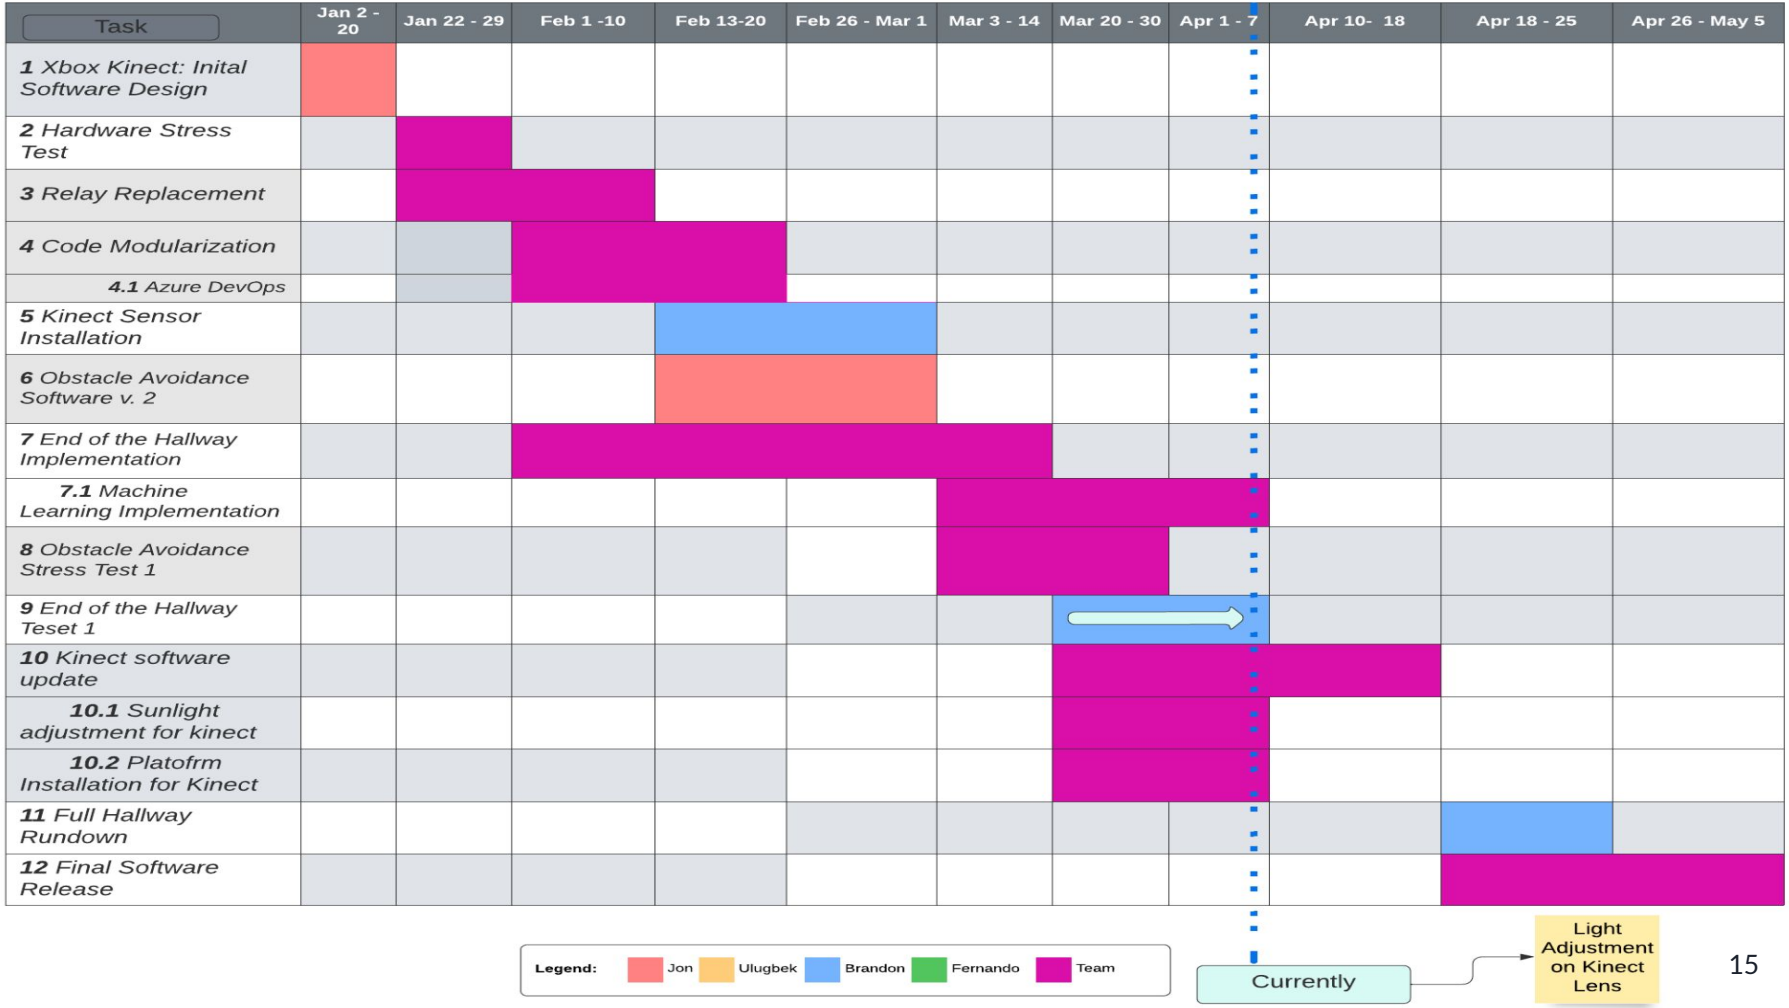


Testing Plan

- Unit and Integration testing is used to ensure full functionality of the thirty-gallon robot.
- Computer Vision is integrated with Obstacle Avoidance.
- Several components working together will power the robot.
    - Such as the motor drivers and the raspberry pi
    - Also the autonomous movement and the obstacle avoidance, must work in sync with each other.
    - Computer Vision is a subset of Obstacle Avoidance, and will scan for appropriate obstacles and possible end of the hallway.
- Qualitative testing will be conducted to ensure end-user satisfaction

Implementation Timeline

Thirty-Gallon Robot



Conclusion

- Cheaper implementation of robotics can open learning opportunities
- Dr. Leverington is looking for an initial software architecture as proof of concept
- Team Poseidon Wayfinding is currently implementing obstacle avoidance and autonomous movement
- Raspberry Pi module and integration of machine learning can enhance performance
    - Future teams and stakeholders can further develop the software architecture

THANK YOU
